### 1. Correct Installation - Gallops

#### Front elevation

#### Procedure

1. Having selected your site, excavate a section 3.00 metres wide by 0.55m/22" deep. The excavated spoil can be mounded on either side of the section, taking care to allow sufficient distance that it doesn't fall back in.
2. Excavate three 150mm/6" trenches, equally spaced at the bottom of the section, to accommodate 100mm / 4" diameter perforated plastic drainage pipes.
3. Carefully install the pipes, ensuring that there is sufficient natural flow, along each pipe.
4. Back-fill the bottom of the section, with 40mm grade washed stone. Using a vibrating roller, compact to a depth of 175 – 200mm / 7" – 8".

5. Install a further layer of 20mm scalplings on top of the 40mm washed stone and compact with a roller.
6. Install Melcourt equestrian surface, to a compacted depth of 250mm/10". Compact the surface material, whilst it is being layered, using a vibrating roller. You might decide to lay a geo-textile sheet between the 20mm scalplings and the Melcourt product. It may be necessary to moisten the material using a water bowser.

### 2. Correct Installation - Arenas

#### Side elevation

#### Procedure

1. As 1 above, for Gallops
2. As 2 above, for Gallops
3. Erect the arena fencing, as above and in accordance with suppliers instructions. Ensure that there is no gap between the bottom rail and the kick board, as this could become a potential foot trap.
4. Complete the installation as 3 – 6 above, for Gallops

### **3. Correct On-Site Aftercare**

#### General Information

1. To ensure peak performance and a long service life, your Melcourt equestrian surface must be installed and maintained in accordance with the following simple instructions.
2. The initial installation of your Melcourt equestrian surface must be watered and well rolled before use. The surface material will compact down by 15 – 20%, which is quite normal and a feature of these types of products.
3. The surface will take between 3 – 10 weeks to reach peak condition. Rolling must continue daily, together with watering, until the surface is 'firm' but not yielding.
4. Every day after use, the surface must be levelled, either by hand raking or mechanically with a grading mesh or roller mounted tines. A constant surface depth must be maintained to ensure uniform footing for the horse.
5. Rolling is best carried out after each levelling.
6. Watering is essential for the surface to remain firm. Natural rainfall will normally be sufficient. As a precautionary measure, water artificially if more than 75mm / 3" of the surface depth becomes excessively loose.
7. The surface should only require topping up when the product is fatigued.

### **Maintenance Requirements**

#### **Daily**

1. Remove all solid droppings
2. Rake and level all deep depressions
3. Level the entire surface with a grading mesh or with roller mounted tines, taking care not to penetrate the surface depth by more than 50mm / 2". Alternate the direction of each grading.
4. Roll the surface evenly and thoroughly.
5. If the surface is used for jumping, the jumps must be re-sited daily to enable take-off and landing areas to resettle to a firm surface before jumping on again.

#### **Weekly**

1. In the event of the surface not having been used for several days, give it a good extra rolling, preferably after a shower of rain.
2. Walk over the area to ensure that no hard or soft spots have developed. If hard, add additional material. If soft, check the drainage or whether the surface is too dry.

#### **Six monthly**

1. Sample check the surface by digging small inspection holes down to the membrane layer. If the surface is less than 150mm / 6" deep, a top up quantity must be added. Replace excavated material and thoroughly compact each hole.

#### **Topping Up**

If sections of the surface have been severely worn, i.e. practically to dust, this material must be removed before new material is added. Maintain the surface as for a new installation.

#### **Freezing**

Melcourt equestrian surfaces have a high tolerance to sub-zero temperatures. However, should extreme temperature conditions prevail, these adverse effects can be minimised by spreading ½ kilogram of sand free agricultural salt per square metre of surface.
